1.0 Introduction

This document describes the features and operation of the Secure Hashing Algorithm 256-bit (SHA256) accelerator utilizing an AXI4-Lite interface.

1.1 Features

- AXI4-Lite interface
- Intermediate hash completion in 71 cycles
- Interrupt support
- Big and small endian configuration parameters
- Xilinx drivers

1.2 Functional Description

The AXI SHA256 accelerator has one control/status register, a register indicating the current progression of the hash, a message block buffer, and the output hash registers. The accelerator can hash one message block (512-bit block) at a time – the maximum size of one block per the SHA256 specification. All that is required to hash a block is to load the entire message size into the message size registers and copy over bytes from a subsection of the message located elsewhere in memory to the accelerator registers. The intermediate hash computation is started by setting the UPDATE bit with the completion indicated by the BLOCK_DONE and/or HASH_DONE bits in the control/status register. The process of loading 512-bits (64-bytes) from memory to the accelerator's registers/block-buffer and commencing the intermediate hash is repeated until all the message is hashed.

2.0 Accelerator Specification

2.1 Performance

2.2 Resource Utilization

2.3 Port Descriptions

2.0 Configuration Parameters

C_SHA256_BIG_ENDIAN	CUR_BLOCK, MSG_SIZE, and MSGx registers are in big endian mode. 1 = Big endian mode 0 = Little endian mode (default)
C_SHA256_BIG_ENDIAN_HASH	HASHx registers are in big endian mode. 1 = Big endian mode (default) 0 = Little endian mode
C_SHA256_GEN_PADDER	Generate the padder module in the accelerator. If one isn't generated, then it is up to the drivers to pad the message before loading words into the SHA256_MSGx registers. 1 = Generate padder (default) 0 = Don't generate padder

3.0 Registers

This table lists the address offsets from the base address of the SHA256 accelerator.

Register	Offset
SHA256_CON	0x00
SHA256_MSG_SIZE_L	0x04
SHA256_MSG_SIZE_H	0x08
SHA256_CUR_BLOCK_L	0x0C
SHA256_CUR_BLOCK_H	0x10
SHA256_MSG0	0x14
SHA256_MSG1	0x18
SHA256_MSG2	0x1C
SHA256_MSG3	0x20
SHA256_MSG4	0x24
SHA256_MSG5	0x28
SHA256_MSG6	0x2C
SHA256_MSG7	0x30
SHA256_MSG8	0x34
SHA256_MSG9	0x38
SHA256_MSG10	0x3C
SHA256_MSG11	0x40
SHA256_MSG12	0x44
SHA256_MSG13	0x48
SHA256_MSG14	0x4C
SHA256_MSG15	0x50
SHA256_HASH0	0x54
SHA256_HASH1	0x58
SHA256_HASH2	0x5C
SHA256_HASH3	0x60
SHA256_HASH4	0x64
SHA256_HASH5	0x68
SHA256_HASH6	0x6C
SHA256_HASH7	0x70

SHA256_CON

U	R/W (2)	R/W (2)	R	R/W	R/W
-	HASH_DONE	BLOCK_DONE	BUSY	UPDATE	EN
[31:5]	[4]	[3]	[2]	[1]	[0]

bit 31-5 **Unimplemented:** Read as '0'

HASH_DONE: Hash of message done status bit (2)
bit 4 1 = Hash of message is done
0 = Hash of message is not done

BLOCK_DONE: Hash of message block done status bit (2)
bit 3 1 = Hash of message block is done
0 = Hash of message block is not done

BUSY: Hash computation in progress status bit
bit 2 1 = The hash computation is in progress
0 = There is no current process running

UPDATE: Start hash of message block control bit
bit 1 1 = Start intermediate hash
0 = Don't start intermediate hash (1)

EN: SHA256 enable control bit
bit 0 1 = The module is enabled
0 = The module is disabled, and all internal states are reset

(1) This bit is automatically cleared by the hardware. For acknowledgement of an update, the busy bit should transition from a '0' to '1'.
(2) The HASH_DONE and BLOCK_DONE bits can only be cleared with '0' after they are '1' to acknowledge the completion. See section 4.4 for more details.

4.0 Operation

4.1 Overview

1. Enable accelerator by setting the EN bit in the SHA256_CON register
2. Load message size (MSG_SIZE) into SHA256_MSG_SIZE_L and SHA256_MSG_SIZE_H registers
3. Load the 16 message block registers with the next 16 words of the message
4. Set the UPDATE bit in the SHA256_CON register
5. Wait for the BLOCK_DONE bit in the SHA256_CON register to go high
6. If the HASH_DONE bit in the SHA256_CON register is high, then copy the HASHx values and acknowledge the completion by clearing the HASH_DONE bit. If the HASH_DONE bit is low, then repeat steps 3-6 and acknowledge the BLOCK_DONE bit by clearing it

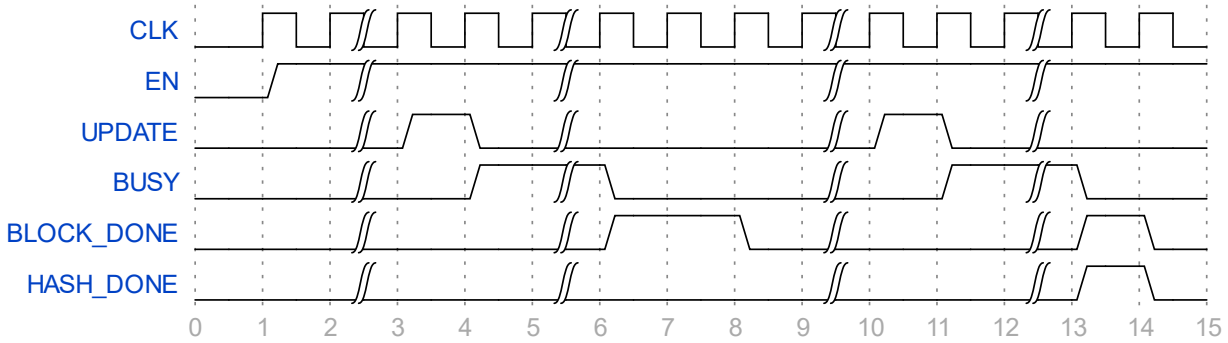

Figure 2: Hash of a message requiring 2 message blocks

The example waveform above shows the hash of a message requiring two message blocks. First, the accelerator is enabled, then between time step 2 and 3, the message size and message block registers were loaded (SHA256_MSG_SIZE_L, SHA256_MSG_SIZE_H, and SHA256_MSG0 through SHA256_MSG15). At timestamp = 3, the UPDATE control bit is set and acknowledged on the following clock when the BUSY status bit transitions from low to high. Between timestamps 5 and 6, the hash is being computed, were on timestamp 6, BUSY goes low and the BLOCK_DONE status bit goes high. The BLOCK_DONE bit is acknowledged on timestamp 8, and the remainder of the message words were loaded into the SHA256_MSGx registers between timestamps 9 and 10. Another UPDATE was issued, and the last message block hash was started. Finally, between timestamps 12 and 13, the message hash completed with the HASH_DONE and BLOCK_DONE status bits going high, then being acknowledged on timestamp 14.

4.2 Enable bit

The EN bit (SHA256_CON[0]) globally enables the accelerator. When enabled, it allows for hashes to be computed. When disabled, it holds the accelerator in a reset state.

4.3 Update and busy bits

The UPDATE bit (SHA256_CON[1]) starts the hash computation given that the module is enabled. When set, it is automatically cleared on the next cycle and is only acknowledged when the BUSY bit transitions from ‘0’ to ‘1’. Once the hash computation has begun, it cannot be paused and the BUSY

bit (SHA256_CON[2]) goes high. Until the BUSY bit goes low and the BLOCK_DONE (SHA256_CON[3]) and HASH_DONE (SHA256_CON[4]) bits are acknowledged (written with ‘0’s) will the UPDATE bit be acknowledged. This means before any other intermediate hash computation can begin, the previous hash needs to have finished and its completion needs to be acknowledged.

4.4 Block and hash completion bits

The BLOCK_DONE and HASH_DONE indicate the completion of a message block hash and message hash, respectfully. Once either are set, they block further updates from occurring (as with the BUSY bit). When only the BLOCK_DONE bit is high, this indicates that the hash computation is not complete, requiring at least one more intermediate hash completion. This bit should be acknowledged by clearing it to allow the UPDATE control bit to be acknowledged to successfully start the hash. If the HASH_DONE bit is high, then the BLOCK_DONE bit will also be high. If a hash of another message is desired, this bit should be cleared. By clearing the HASH_DONE bit, it also clears the BLOCK_DONE bit and resets the accelerator state. However, the HASHx registers will remain unchanged to allow for the software drivers to copy the results before or after acknowledging the HASH_DONE bit, but before the start of the next hash.

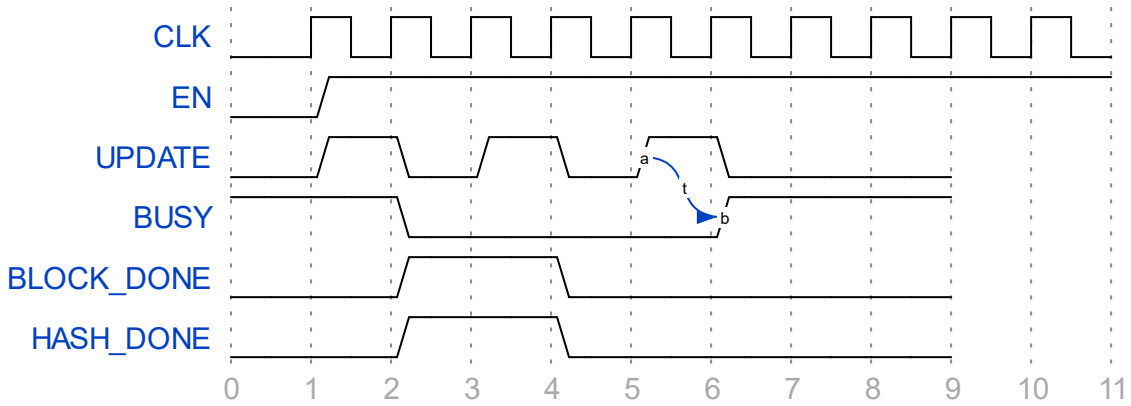

Figure 3: UPDATE acknowledgement

The waveform above shows scenarios where an update issue was ignored and where it was accepted. At timestamp 2, the update issue was ignored because the BUSY bit was high. Likewise, at timestamp 4, the update issue was ignored because the BLOCK_DONE and HASH_DONE bits were high, although the update request could have been ignored if only either one of them were high. Finally, in timestamp 6, the update request was accepted as the BUSY bit transitions from ‘0’ to ‘1’.

4.5 Message size registers

SHA256_MSG_SIZE_L and SHA256_MSG_SIZE_H together make up the message size, MSG_SIZE, a 64-bit parameter. MSG_SIZE is the size of bytes in the message to be hashed where SHA256_MSG_SIZE_L holds the lower 32 bits and SHA256_MSG_SIZE_H holds the upper 32 bits for both endianness.

4.6 Current block registers

SHA256_CUR_BLOCK_L and SHA256_CUR_BLOCK_H together make up the current block, CUR_BLOCK, a 55-bit parameter. SHA256_CUR_BLOCK_L is the lower 32 bits of CUR_BLOCK and

SHA256_CUR_BLOCK_H is the upper 23 bits. CUR_BLOCK indicates the block currently being hashed, where a block is a 512-bit, or 64-byte, section of the overall message. CUR_BLOCK is used to indicate the progress of the hash and can be used by software drivers to load the correct data from the message into the message block registers (SHA256_MSGx). It can also be used as a secondary source for indicating the end of hash. The message size in bytes and last block are related by the following expression:

Last Block = MSG_SIZE >> 6

4.7 Message block registers

The SHA256_MSGx registers make up the 512-bit message block. Not all registers need to be filled as long as the message size (MSG_SIZE) is correctly set. For example, consider a message that has 2 words in its last block. It's message size's lower 6 bits should read '001000'. This isn't a concern if the message size is correctly calculated – the hardware will know when to stop reading. If the message is not word aligned, i.e. its message size is not an even multiple of 4, then the unused bytes are don't-cares and are not a concern for the software – just simply load in the data and the size.

4.8 Hash registers

The SHA256_HASHx registers contain parts of the full 256-bit hash. The full hash is found through concatenation in the following order (dropping the SHA256_ prefix):

HASH0 | HASH1 | HASH2 | HASH3 | HASH4 | HASH5 | HASH6 | HASH7

6.0 Interrupts
